

The dictionary definitions are too vague to really help me decide this, so I instead relied on this rule of thumb: if it can be done better, it's a craft.

By that metric, I would call this piece primarily ART. There is definitely a level of craftiness that goes into making it, as the brush strokes and other technical aspects of paintings are definitely skills that can be learned and refined, but there is no clear way to *improve* this painting without just making a *different* painting.

What immediately caught my eye was the contrast between the deep, red textures and the glowing yellow circle that feels like a sun. I don't typically get emotional when looking at art, and this piece was no exception. I think the artist might be expressing some emotional or psychological turmoil based on the crashing black and red brush strokes. Regardless of whether that was the artist's intent, that is what I take away from it.

I believe Artificial Intelligence could generate something visually similar, but in doing so, would innately lack the chaotic feeling that this piece since it would be a programmatic approach to setting the visuals.

In terms of software design, this makes me think about balancing function with intention. Software (almost) always has room for technical improvement, cementing it as a craft in my mind, but the purpose behind creating a program itself would be an art to me. Code fundamentally is, should, and will

always be a craft, but the overall design of a software can freely include artistic interpretations.

When I write code, I try to make it not only correct but also readable, efficient, and maintainable. I often revisit and refactor it after it works, because the “working” version is often just the first draft that I continue to improve on until either some deadline or if it’s a personal project, until I lose interest in it.
